MODERN CRYPTOLOGY

LECTURE 16

# PROPERTIES OF PHYSICAL SIGNATURE

- A physical signature has two key properties:
  - ① Forgery is difficult, and
  - ② Correctness can be verified by anyone with training.
- Can the same be replicated in digital domain?
- Leads to the notion of **digital signatures**.

# DIGITAL SIGNATURES

- Given a digital document  $m$ , Anubha can append string  $s$  to  $m$  such that:
  - ▶ Replacement of  $m$  by a different document or signing  $m$  with Anubha's signature is hard for anyone except Anubha.
  - ▶ Braj, or anyone else, can verify that  $s$  is “signature” of Anubha associated with  $m$ .
- Public-key encryption algorithms can often be adopted for this.

# DIGITAL SIGNATURE VIA RSA

- Anubha announces her public key  $(e, n)$  and she has corresponding private key  $d$ .
- Assume that document  $m$  can be viewed as a number  $< n$ .
- **Signing:** Anubha computes  $s = m^d \pmod{n}$ .
- **Verification:** Given  $(m, s)$ , Braj checks if  $s = m^e \pmod{n}$ .
- Hardness of forgery follows from properties of RSA encryption.

# DIGITAL SIGNATURE VIA ECC

- Anubha announces her public key  $(C, p, P, eP, t)$  and she has  $t - e$  as private key.
  - ▶  $g$  is an element of order  $t$  in the group and  $t$  is a prime number.
- Assume that document  $m$  is a number with  $1 < m < t$ .
- Signing:
  - ▶ Anubha picks a random  $r$ ,  $1 < r < t$ , and computes  $rP = (a, b)$ .
  - ▶ She computes  $s = r^{-1}(m + ae) \pmod{t}$ .
  - ▶ Signature of document  $m$  is the pair  $(a, s)$ .
- Verification:
  - ▶ Given document  $m$  and signature  $(a, s)$ , Braj first computes  $s' = s^{-1} \pmod{t}$ .
  - ▶ Then he computes point  $s'mP + s'a(eP) = (a', b')$ .
  - ▶ He accepts the signature if  $a = a'$ .

# DIGITAL SIGNATURE VIA ECC

- Correctness:

$$(a', b') = s'mP + s'a(eP) = s'(m + ae)P = rP = (a, b).$$

# DIGITAL SIGNATURE VIA ECC: SECURITY

- Changing  $m$  while keeping signature  $(a, s)$  same is not possible:
  - ▶ Fixing  $a$  fixes  $r$ .
  - ▶ Therefore, if  $m$  changes, so does  $s$ .
- Creating signature  $(a, s)$  of document  $m$  appears as hard as computing private key  $e$ :
  - ▶ Signature  $(a, s)$  of document  $m$  satisfies the equation

$$m = rs - ae \pmod{t},$$

where  $rP = (a, b)$ .

- ▶ If Ela can compute  $r$  and  $s$  satisfying above, then she can compute  $e = (rs - m)/a \pmod{t}$ .
- ▶ It is not clear how can Ela compute  $a$  and  $s$  without knowing  $r$ .

# DIGITAL SIGNATURE VIA ECC: SECURITY

- It is essential that for every signature, a random  $r$  is chosen.
- If same  $r$  is used for signing documents  $m$  and  $m'$  resulting in signatures  $(a, s)$  and  $(a, s')$  respectively, then:

$$m = rs - ae \pmod{t}$$

$$m' = rs' - ae \pmod{t}$$

- Therefore,

$$ms' - m's = ae(s - s') \pmod{t},$$

giving

$$e = \frac{ms' - m's}{a(s - s')} \pmod{t}.$$

# DIGITAL SIGNATURE POST QUANTUM COMPUTERS

- Previous signatures schemes become insecure in the presence of quantum computers.
- The NIST contest has shortlisted three candidates for digital signatures, two of which are based on integer lattices.
